

HD2102.1 - HD2102.2

HD2102.1, HD2102.2 PHOTO-RADIOMETERS

HD2102.1 and HD2102.2 are portable instruments with LCD display. They measure illuminance, luminance, par and irradiance (across VIS-NIR, UVA, UVB and UVC spectral regions or measurement of irradiance effective according to the UV action curve).

The probes are equipped with the SICRAM automatic detection module: in addition to detection, the unit of measurement selection is also automatic. The factory calibration data are already stored inside probes.

In addition to instantaneous measurement the instruments calculate the acquired measurements time integral Q(t). Some thresholds can be associated with the integrated measurement and with the integration time, which can be set in the menu. When exceeded, these thresholds cause the instrument to stop the integral calculation.

The HD2102.2 instrument is a **datalogger**. It memorizes up to 38,000 samples with single probes and 14,000 with combined probes. Data can be transferred from the instrument connected to a PC via the RS232C serial port or USB 2.0 port. The storing interval, printing, and baud rate can be configured using the menu.

Both models are fitted with an RS232C serial port and can transfer the acquired measurements in real time to a PC or to a portable printer.

The **Max**, **Min** and **Avg** function calculate the maximum, minimum or average values.

Other functions include: the relative measurement REL, the HOLD function, and the automatic turning off that can also be disabled.

The instruments have IP66 protection degree.

Relative spectral response

The radiometric probe **LP471BLUE** measures irradiance (W/m²) in spectral band of blue light. The probe consists of a photodiode plus an appropriate filter and it is provided with diffuser for proper measure in accordance with the cosine law. The spectral response curve of the probe allows to measure the radiation effective for damages caused by blue light (curve B(λ) according to the standards ACGIH / ICNIRP) in the spectral range from 380 nm to 550 nm. The radiation optics in this portion of the spectrum can produce photochemical damage to the retina. Another field of application is the monitoring of the probe irradiance from blue light used in the treatment of neonatal jaundice.
